

Stage 4A-Lite: Rapid Persona Brief

P-033: Tiny Home / Alternative Housing Resident

Pipeline: Micro-Trends Identity | **Trend:** MT-12 (Van Life / Mobile Living Identity) **Quadrant:** INVEST | **P1:** 3.65 | **P2:** 4.50 | **Confidence:** 3 | **Composite:** 2.61 **Demand Window:** 24–36 months | **Date:** 2026-03-10

Section 1: Demand Snapshot

What Is the Demand Signal?

The tiny home and alternative housing segment has shifted from novelty to lifestyle identity. What began as a DIY counterculture response to housing costs has become a mainstream identity movement with dedicated media, zoning coalitions, and commercial infrastructure. The signal is no longer “people are living in tiny houses” — it is “people are publicly identifying as tiny home residents and organizing their consumption around that identity.”

The connectivity gap is specific and underserved: tiny home residents are stationary (unlike van lifers) but live outside standard broadband infrastructure. They cannot get cable internet at a rural lot, an ADU, or a tiny home community parcel. They rely on cellular data as primary home broadband — yet no carrier has ever designed a plan, a brand, or a product feature for this exact use case. They are invisible to the residential internet market and treated as an afterthought by mobile carriers.

What Triggered This Opportunity?

Three reinforcing forces:

- Housing affordability crisis sustaining the movement.** U.S. median home prices reached \$419,200 in Q4 2024 (NAR, 2025), the highest inflation-adjusted level on record. For younger buyers — particularly women, who skew 55–77% of tiny home adopters — a 200–400 sq ft structure on a purchased lot is an achievable path to ownership. The financial logic is durable.
- Zoning reform expanding the addressable geography.** As of 2025, over 20 states have enacted ADU-permissive legislation, including California (SB 9/10), Washington, Oregon, and Florida (Freddie Mac, 2025). This is expanding the viable population from rural/exurban lots to urban backyards — growing the addressable market from a rural niche to a suburban mainstream.
- Identity crystallization through media and community.** The Tiny House Nation franchise (Netflix/FYT), Exploring Alternatives YouTube (1.2M+ subscribers), r/TinyHouses (180K+ members), and Tiny Home Industry Association (THIA) annual summits have created the media and community infrastructure of an established lifestyle identity. People are not just living tiny — they are publicly performing the values of minimalism, sustainability, and intentional living.

Addressable Population and Window Duration

Core addressable population: 500K–1M tiny home/alternative housing residents (SkyQuestt, 2025: \$32.2B global tiny homes market; U.S. share ~40%; estimated 500K–1M owner/resident units based on market size and unit counts). This is the existing installed base.

Annual new entrants: ~80,000–120,000 new tiny home units placed annually in the U.S. (THIA, 2024). Each represents a household newly entering the connectivity gap — the primary acquisition moment.

Adjacent population (moment-extended): ADU residents represent 3–4M occupied accessory dwelling units nationally (Freddie Mac, 2024), many of which face the same primary broadband gap. Broadening the frame to “alternative and non-standard housing connectivity” expands the addressable opportunity materially.

Window duration: 24–36 months. Housing affordability headwinds are structural, not cyclical. Zoning reform momentum is bipartisan and accelerating. The window risk is not demand fading — it is that a mainstream carrier (Verizon, with its existing RV prepaid positioning) or a well-capitalized MVNO recognizes the gap and enters first. Competitive timing, not demand timing, defines the window boundary.

Decay indicators to watch: Meaningful decline in tiny home unit shipments (THIA quarterly data), a major carrier launching an identity-specific alternative housing plan, or a fixed wireless broadband provider (T-Mobile Home Internet, Starlink) pricing specifically for tiny home communities.

Section 2: Core Factor Analysis

Persona name: Maya. She/her. 32 years old. Lives in a 280 sq ft custom-built tiny home on a leased rural lot in the Appalachian foothills outside Asheville, NC. Works remotely as a UX designer for a healthcare startup. Moved from a 950 sq ft apartment in Charlotte 18 months ago. No car payment, no mortgage, no streaming bundle she didn't choose. Has an AT&T unlimited plan she switched to from Verizon after the move because AT&T had marginally better signal on her road — but the hotspot cap is making her increasingly frustrated.

Factor 2: Spending & Financial Habits

Quantitative context

Tiny home residents report median total monthly expenses of \$1,400–\$1,800 including land lease, utilities, and loan service, compared to \$2,800–\$3,200 for conventional apartment renters in comparable markets (Tiny Home Industry Association, 2023). This financial optimization is deliberate and identity-reinforcing — they track expenses, evaluate subscriptions ruthlessly, and hold strong opinions about value-for-money. Connectivity spend is one of the few non-negotiable line items: 68% of tiny home residents report cellular data as their primary home internet (Forbes Home, 2023). Monthly wireless spend averages \$85–\$110 for hotspot-heavy users, compared to \$45–\$65 for typical U.S. wireless subscribers (J.D. Power, 2024). They overpay for connectivity relative to their needs because no plan was designed for their use case.

Q2.1 What does your monthly budget look like, and where does your wireless bill fit in?

“Land lease is \$350, tiny home loan payment is \$480, utilities are \$60 in summer. My phone bill is \$95 — more than my electric. That feels backwards. But I can't work without it, so it's non-negotiable. Everything else I can cut. The phone bill I cannot.”

Q2.2 Do you evaluate your wireless plan carefully, or does it auto-pay and disappear?

“I reviewed it hard when I moved. I ran coverage map comparisons for two hours — which felt insane but was completely necessary. AT&T won by a thin margin for my address. I haven't revisited it since because switching feels risky. I'd rather overpay slightly for something I know works than gamble with my only internet connection.”

Q2.3 Have you tried to use hotspot as your home internet? What happened?

“It IS my home internet — that's not supplemental, that's it. The cap throttles to 600 Kbps after 50GB. Figma at 600 Kbps is unusable. I've been borrowing Starlink from my neighbor for emergencies and front-loading heavy downloads before the cap hits. It's a whole system I built that I shouldn't need.”

Q2.4 How do you feel about what you're paying relative to what you're getting?

“Frustrated. I'm paying a premium postpaid rate for a product designed for someone with home WiFi who uses hotspot a few times a month. My hotspot is my home WiFi. Completely different use cases, exactly the same price. That asymmetry bothers me more than the dollar amount itself.”

Q2.5 If a plan existed explicitly designed for tiny home residents as primary internet — what would you pay?

“\$110 to \$130, comfortably. The Starlink I'm piggybacking on costs \$120. If cellular delivered equivalent reliability with no cap anxiety, that's worth the same money. What I won't pay for: streaming bundles I already have, perks I'll never use. Give me reliable hotspot and honest coverage data. That's it.”

Factor 3: Needs & Aspirations

Quantitative context

Stated needs are straightforward: reliable primary broadband in a non-standard housing structure. But the identity dimension is richer. Tiny home residents score 2x higher likelihood of holding graduate degrees than the general population (THIA, 2023) and self-describe overwhelmingly (83%) as motivated by “intentional living” and “values alignment” rather than purely financial necessity (THIA Consumer Survey, 2023). They are not reluctant alternative housing residents. They chose this deliberately. They want their consumption choices — including carriers — to reflect and reinforce who they are. The unstated need is recognition: a brand that sees them as a legitimate, intentional consumer rather than an edge case the plan never anticipated.

Identity aspiration: To live consistently with stated values — minimalism, sustainability, self-sufficiency — all the way down to the infrastructure layer. A carrier that requires a permanent street address and prices for urban data usage patterns is, to Maya, a daily friction that signals misalignment between who she is and the systems she depends on.

Self-perception gap: Maya thinks of herself as technically capable and financially intentional. Her current workaround system — tracking hotspot usage manually, borrowing Starlink, front-loading downloads — is competent but embarrassing. She has built a life of exceptional intentionality and is managing her internet connection like it's 2012. That gap creates low-level but persistent dissatisfaction.

Q3.1 Why did you choose alternative housing? What were you trying to build?

"I wanted to own something without a 30-year mortgage for a house I didn't need. I wanted my life to cost less than it earns — which sounds obvious but turns out to be rare. Living here lets me take design contracts I actually find interesting. The tiny home is what makes that possible."

Q3.2 What does the tiny home community mean to you beyond the housing itself?

"It's the most genuinely values-aligned community I've found. People thinking about energy use, material choices, what they actually need. I feel less crazy for caring when I see thousands of people caring too. It's affirming in a way my old apartment building never was. That community is part of why I chose this."

Q3.3 What would it mean if your wireless carrier understood your situation — not as an edge case, but as a designed-for customer?

"I'd tell everyone in the community immediately. I don't expect companies to see me — I've built workarounds for ways mainstream products don't fit. But a carrier saying 'we know hotspot is your home internet, here's a plan for that' would spread through r/TinyHouses fast. We talk about this stuff constantly."

Q3.4 What does your connectivity situation prevent you from doing?

"Heavy screen share days are stressful — I'm managing bandwidth anxiety on client calls. I've driven to the library for really intensive design reviews. I also can't build the smart home setup I want. A few sensors plus laptop tethering eats my cap too fast. The data cost paranoia holds back things I'd otherwise do."

Q3.5 Best case — what does your connectivity look like in two years?

"Unlimited hotspot at real speeds so I stop thinking about it. IoT for energy monitoring, door sensors, temperature control — all on one data pool, cheap. Honest coverage maps before I move my home to a new lot. Maybe a community layer where I can see coverage reports from actual users near my coordinates."

Factor 4: Fears & Pain Points

Quantitative context

The connectivity pain in this segment is structural, not incidental. 68% rely on cellular as primary home internet (Forbes Home, 2023). Hotspot throttling is the #1 technical complaint: standard postpaid unlimited plans cap hotspot at 15–50 GB before throttling to 600 Kbps, making high-bandwidth work tasks impossible (PCMag carrier comparison, 2025). Coverage uncertainty is the #2 complaint: coverage maps are modeled propagation estimates, not ground-truth measurements, and tiny home lots frequently sit at rural road termini or in terrain valleys where tower signal degrades below carrier estimates. 43% of tiny home residents report coverage as a "significant concern" when selecting new land (THIA, 2023). The emotional dimension of both fears is control — these are people who chose alternative housing specifically to gain control over their lives, and their most critical infrastructure tool is one they cannot fully trust or manage.

Q4.1 What is your biggest connectivity fear day-to-day?

"Throttle day. Usually around the 22nd of the month — I can feel it before I check the app. I start rationing what I can and can't load. There's a low-grade dread around client calls after the cap hits. My career runs on this connection. That dread is there every month and it shouldn't be."

Q4.2 Have you had a connectivity failure that actually affected your work?

"Once. Starlink outage on my neighbor's side, and I simultaneously hit the throttle limit, during a design review with four stakeholders. I drove to the library parking lot at 6 PM and finished the call on library WiFi through the window. I got through it, but I had an anxious shame spiral for two days after."

Q4.3 How do you feel about coverage map information from carriers?

“I don’t trust it. Every carrier showed ‘Good’ or ‘Excellent’ at my coordinates when I was researching. Reality is adequate in my living area, one bar on the far side of the property. I rely on community forums — r/TinyHouses, Asheville threads — for actual field reports. Carrier maps are aspirational, not informational.”

Q4.4 What worries you most if you need to move your tiny home to a new lot?

“Starting coverage research from scratch. My whole setup — signal booster, antenna position, knowing where the tower is — is calibrated to this specific spot. I’ve actually factored carrier coverage into potential next locations because I can’t afford to get it wrong. That’s too much cognitive load just to maintain my internet.”

Q4.5 Are there connectivity limitations you’ve accepted as permanent?

“Smart home stuff — I’ve given up on a proper IoT setup because the per-device data paranoia is real. I don’t livestream or do video content even though I’d like to, because upload bandwidth isn’t reliable enough. And I’ve accepted I’ll never have a carrier that actually fits. I figured that out early. I just manage.”

Factor 5: Product Landscape & Switching Behavior

Quantitative context

The current wireless product landscape is a mismatch at every level. Postpaid unlimited plans (AT&T, Verizon, T-Mobile) are designed for users who have home WiFi — hotspot is a secondary cap, not a primary service. Home wireless internet products (T-Mobile Home Internet at \$50/month, Verizon Home Internet at \$50–70/month) offer unlimited data but have coverage gaps in rural and exurban areas that heavily overlap with tiny home placement. Starlink (\$120–\$150/month) is reliable but expensive, requires physical installation, and has a portable/residential billing complication for users who move. No carrier or MVNO has targeted this segment directly. The JTBD gap score of 5 in Stage 3 is accurate: this is genuinely unserved territory.

Switching behavior profile: Carrier Mobility score of 4. These consumers switched at the time of their move (TR-06, Interstate Relocation, Intent 3.6), are willing to switch again for a genuinely better-fit option, but require evidence before switching. Coverage reliability is the dominant criterion. Brand identity is a secondary factor — strong positive signal if the carrier speaks their language, but insufficient alone to drive a switch.

Q5.1 What is your current wireless setup, and how did you end up there?

“AT&T unlimited postpaid, \$95 a month. I drove out to the lot with three SIMs and tested signal before I committed. AT&T won at my coordinates. It was not a brand decision — it was a signal decision. I have zero loyalty to AT&T. They just happened to have the best tower placement for my spot.”

Q5.2 What would it take for you to switch carriers?

“Ground-truth coverage data for my specific address — not a propagation model, measurements from actual users near my coordinates. And unlimited hotspot at real speeds. If those two things check out, I’d move within a week. I switched from Verizon to AT&T fast when I moved. I can do it again. Uncertainty stops me, not loyalty.”

Q5.3 Have you looked into T-Mobile Home Internet or Starlink as alternatives?

“T-Mobile Home Internet isn’t available at my address — rural gap. Starlink I’m using informally through my neighbor. I’d pay for it directly if the portable plan was clearly month-to-month and portable when I move the home. The installation hassle and billing uncertainty are what’s stopped me. Too complicated to evaluate properly.”

Q5.4 How do you use your current plan across devices? What feels missing?

“Phone is central. Laptop tethers to hotspot, which hits the cap fast. I’d love IoT sensors — smart energy monitor, door sensor — but there’s no clean way to do it without burning data and paying per device. No carrier has a multi-device pool that makes sense for someone with zero home WiFi. That gap is real.”

Q5.5 If you found a carrier clearly built for tiny home residents, would you recommend it?

“Immediately. r/TinyHouses asks about connectivity solutions constantly — it’s a top-5 topic. If I found something that worked, I’d write a detailed post: actual data usage, coverage test results from my lot, cost breakdown. That’s how decisions get made here. We don’t trust advertising. We trust each other’s specific, on-the-ground reports.”

Section 2B: Switching Profile Module

P-033 has a primary acquisition moment tagged in Stage 2: TR-06 (Interstate Relocation, Intent 3.6, Window: Short). The persona has moment enrichment. Switching Profile Module applies.

Dimension 1: Trigger Mechanism + Force Score

Trigger mechanism: Evaluation window. The move to an alternative housing structure is a voluntary life transition rather than a forced structural event. Unlike divorce (forced plan dissolution) or job loss (employer plan termination), the tiny home move does not automatically dissolve the current carrier relationship. However, the move creates a high-urgency re-evaluation: coverage at the new location is unknown, the old plan may not perform, and the subscriber is actively shopping for a new provider. This is an open evaluation window with elevated switching intent.

Switching force score: 3 out of 5. TR-06 (Interstate Relocation) carries Intent 3.6 in the Trigger Event Library — below the 4.0 threshold for forced-dissolution scoring. The window is real and motivating but requires a compelling product offer to convert; inertia is lower than for forced-switch moments but still present.

Compound trigger mapping: For tiny home movers specifically, the trigger compounds above TR-06’s baseline. The combination of (1) geographic relocation creating coverage uncertainty, (2) the move from a conventional broadband-available address to a non-standard address without cable/fiber access, and (3) the identity formation moment of committing to alternative living creates a reinforcement pattern where connectivity re-evaluation is not merely convenient — it is necessary. The subscriber cannot simply stay on their current plan and hope it works; they must actively verify coverage and often discover their existing plan architecture (hotspot as supplemental, not primary) is wrong for the new situation.

Emotional state tag: Empowered + Anxious. The move is a deliberate empowerment choice. The connectivity uncertainty that accompanies it is genuinely anxious. Both states are present simultaneously — confident about the lifestyle decision, uncertain about the infrastructure.

Dimension 2: Annual Volume + Seasonal Distribution

Total annual volume: 80,000–120,000 new tiny home units placed annually in the U.S. (THIA, 2024), representing the primary cohort of evaluation-window switchers. At an average household size of 1.6 persons per tiny home unit (THIA Consumer Survey, 2023), this translates to 128,000–192,000 individuals annually entering the TR-06 evaluation window via a tiny home move. The broader ADU cohort adds an estimated 200,000–300,000 new ADU occupants annually (Freddie Mac, 2024), though switching intent is lower for ADU residents who may retain the primary residence connection.

Seasonal distribution: Tiny home placement follows construction and real estate seasonality. Quarterly estimate:

Quarter	Months	Share	Notes
Q1	January–March	~15%	Winter construction lag
Q2	April–June	~30%	Spring surge, peak construction season
Q3	July–September	~35%	Peak placement season
Q4	October–December	~20%	Fall completions before winter

Peak switching window: late April through September, with the highest intent concentration in May–August when construction completions peak and new residents are settling in.

Year-over-year trend: Growing. THIA reports 15–20% compound annual growth in tiny home unit shipments from 2021–2024 (THIA, 2024). ADU permitting approvals increased 27% year-over-year in California alone following SB 9 implementation (California Department of Housing, 2024). Zoning reform expansion to 20+ states projects continued growth. Trajectory: Growing, 3-year view.

Dimension 3: Interception Channels (Ranked by Window Fit)

Rank	Channel	Type	Rationale
1	Tiny home community subreddits and forums (r/TinyHouses 180K+ members, r/tinyhouses_for_sale, THIA community forums)	Digital / Community	Highest reach within the evaluation window; coverage questions are a top-5 recurring topic; zero carrier presence means first-mover captures category ownership. CPA estimated \$40–\$65 per subscriber based on analogous community-first MVNO acquisition costs (Google Fi community referral benchmarks, 2024).
2	Tiny home builder and dealership partnerships (THOW builders: Liberation Tiny Homes, Timbercraft Tiny Homes, etc.)	Partnership	Builders are the point-of-sale moment — a carrier partnership inserts Gather into the evaluation window at the highest-intent point. Timing: the buyer is setting up a new home with no connectivity yet. CPA estimated \$55–\$90 (partner channel).

Rank	Channel	Type	Rationale
3	YouTube and Instagram tiny home content ecosystem (Exploring Alternatives 1.2M, Living Big in a Tiny House 3.9M)	Digital / Influencer	Strong brand awareness channel but lower conversion efficiency. Higher reach, lower contextual intent. Best for top-of-funnel seeding before community and builder channels drive conversion.

CPA benchmarks: - Community channel (r/TinyHouses, forums): \$40–\$65 estimated CPA - Builder/dealer partnership channel: \$55–\$90 estimated CPA

Partnership feasibility (builder/dealer — #1 partnership channel): Incentive alignment is high — builders want to offer a complete move-in solution and connectivity is an explicit customer concern at time of purchase. Activation timeline: a 90-day pilot with 3–5 THOW builders could be operational within a single quarter. Exclusivity potential: meaningful in the short term — first carrier to build a dedicated builder partner program would have 12–18 months before a well-resourced competitor could replicate the distribution footprint.

Dimension 4: Window Structure

Window type: Short. TR-06 is classified as a Short window in the Trigger Event Library. The active evaluation period is the 4–6 weeks surrounding the move-in: before and immediately after settling into the new location. After 6–8 weeks, coverage workarounds are established (signal boosters positioned, neighbor Starlink relationships formed, hotspot management routines built) and the switching urgency dissipates. The subscriber enters a stable-but-frustrated state in which switching requires overcoming inertia rather than meeting an immediate need.

Peak intent window: 2–3 weeks before move-in through 6 weeks after. The pre-move research phase (coverage map comparison, subreddit queries) is the highest-intent moment for brand discovery. The 2-week post-move-in settling period is the highest-intent moment for plan activation — the subscriber now knows what actually works at their address and is ready to commit.

Intent decay curve: Sharp. Once workarounds are established — typically within 60 days of move-in — the urgency to switch drops significantly. A subscriber who has built a functional (if suboptimal) connectivity setup becomes a much harder acquisition target.

Decision journey:

Stage	Timing	What Happens	Interception Opportunity
Awareness	Pre-move	Researching connectivity at new location via forums and coverage maps	Community forum presence — be the answer when they search
Active search	1–2 weeks pre-move-in	Comparing plans, testing SIMs, seeking community recommendations	Community endorsement and builder partner referral
Decision	First 2 weeks post-move-in	Subscriber has verified real-world signal quality and is ready to commit	Product trial, eSIM activation
Post-decision	60+ days	Workaround entrenchment or loyal evangelist	Retention through community belonging and product delivery

Most effective interception point: Community forum presence during the pre-move awareness phase. If Gather is the answer that surfaces when a prospective tiny home resident types “best carrier for tiny home internet” into r/TinyHouses, the conversion window that follows is high-intent and fast.

Section 3: Executive Brief

Key Insights

1. The use case is structurally different, not marginally different. This is not a subscriber who uses hotspot a little more than average. This is a subscriber for whom hotspot IS home internet — the entire connectivity architecture is inverted. Standard carrier plan design (postpaid unlimited with supplemental hotspot cap) is wrong at the product architecture level. Solving this requires a plan built from the ground up for hotspot-as-primary.

2. Trust is earned through transparency, not advertising. This segment verifies carrier claims through peer networks before switching. Coverage maps are explicitly distrusted; community field reports are the decision input. A carrier that publishes real, crowdsourced coverage data at the parcel level — not modeled propagation estimates — would be the first carrier to pass the community’s credibility test. This is a trust arbitrage opportunity.

3. The switching window is short and well-defined. The TR-06 evaluation window (peak: 6 weeks around move-in, force score 3) is actionable through community and builder partnership channels. The move is the moment. After 60 days, the subscriber has adapted and the urgency is gone. Intercept before workarounds calcify.

4. The identity dimension amplifies word-of-mouth disproportionately. This community is high-information, high-trust, and highly communicative. A carrier that earns community endorsement in r/TinyHouses and the THIA ecosystem receives compounding organic acquisition at a fraction of standard MVNO CAC. The inverse is equally true: a carrier that fails visibly in this community will be documented and shared.

5. Multi-device connectivity is an underserved upsell vector. The desire for affordable IoT data (energy monitoring, security, sensors) is explicit and unmet. A plan architecture that includes a small IoT data pool — phones, hotspot, and home sensors on one account — would address a stated aspiration no carrier currently touches for this segment.

Top 3 Needs

1. **Unlimited hotspot at full speed as primary home internet** — not supplemental; the entire connectivity model for this customer is inverted relative to standard carrier plan architecture. This is the core JTBD.
2. **Ground-truth coverage data for specific locations** — parcel-level, user-reported, not modeled. The subscriber cannot afford to get coverage wrong at a rural lot; they need field evidence, not marketing estimates.
3. **Multi-device data pooling including IoT** — a single account covering phone, laptop hotspot, and home sensors at a price point that makes IoT affordable when there is no home WiFi.

Go/No-Go Recommendation

GO — with qualifier.

The P-033 opportunity is commercially sound. P2 scores are among the strongest in the INVEST matrix (4.50), driven by a JTBD gap score of 5 and Differentiation Potential of 5 — no carrier is in this space with an identity-native product. The demand is real, growing, and structurally sustained by housing affordability pressures. Community distribution channels (r/TinyHouses, builder partnerships, YouTube ecosystem) are accessible and yield low-CAC organic growth once community endorsement is earned.

The qualifier is P1 Market Size (score: 2). The core tiny home population (500K–1M residents) is small relative to the investment required for a standalone brand launch. The go case depends on framing: P-033 should not be launched as a standalone micro-brand but as a secondary strand within the MT-12 Van Life / Mobile Living brand architecture already justified by P-031 (Full-Time Van Lifer). The van life persona and the tiny home persona share the same JTBD (cellular as primary internet), the same competitor gap (no carrier serves them with an identity-native product), and overlap substantially in community infrastructure. A single “life without conventional infrastructure” micro-brand can serve both through plan variants differentiated by mobile (P-031) vs. stationary (P-033) use patterns. The combined addressable population (1.5–2M core, 5–7M adjacent with ADU inclusion) is more than sufficient to justify the brand investment.

Switching profile finding incorporated: The Short window (force score 3) and 60-day intent decay curve set a clear operational requirement: interception must happen pre-move or within the first two weeks of move-in. Gather’s distribution advantage is community presence — specifically, owning the answer to “best carrier for tiny home primary internet” in the forums where prospective residents research before and during their move. The builder partnership channel is the highest-ROI strategic investment: inserting Gather into the point-of-sale conversation with THOW builders captures the evaluation window at its highest-intent moment, before workarounds are built.

Proceed to 4B-Rapid. Design 1–2 product concepts within the MT-12 brand architecture, with a plan variant specifically addressing the stationary/hotspot-primary use case. Primary concept: brand and plan architecture that serves both P-031 and P-033 under a “life without conventional infrastructure” positioning. Secondary concept: explore whether a dedicated tiny home sub-brand (within the Gather micro-brand platform) creates enough community signal to warrant separate positioning.

*Report generated: 2026-03-10 Pipeline: Micro-Trends Identity (Stage 4A) Next stage: 4B-Rapid (Micro-Trend Value Prop Designer)
Cross-reference: P-031 (Full-Time Van Lifer — primary persona for shared brand architecture), P-032 (Part-Time Van Lifer — upsell aspiration)*
